ABSTRACT

This chapter introduces a view-based, model-driven approach for process-driven service-oriented architectures. A typical business process consists of numerous tangled concerns, such as the process control flow, service invocations, fault handling, transactions, and so on. Our view-based approach separates these concerns into a number of tailored perspectives at different abstraction levels. On the one hand, the separation of process concerns helps reducing the complexity of process development by breaking a business process into appropriate architectural views. On the other hand, the separation of levels of abstraction offers appropriate adapted views to stakeholders, and therefore, helps quickly re-act to change at the business level and at the technical level as well. Our approach is realized as a model-driven tool-chain for business process development.

INTRODUCTION

Service-oriented computing is an emerging paradigm that made an important shift from traditional tightly coupled to loosely coupled software development. Software components or software systems are exposed as services. Each service offers its functionality via a standard, platform-independent interface. Message exchange is the only way to communicate with a certain service.

The interoperable and platform independent nature of services underpins a novel approach to business process development by using processes running in process engines to invoke existing services from process activities (also called process tasks or steps). Hentrich and Zdun (2006) call this kind of architecture a process-driven, service-oriented architecture (SOA). In this approach, a typical business process consists of many activities, the control flow and the process data. Each activity corresponds to a communication task (e.g., a service invocation or an interaction with a human), or a data processing task. The control flow describes how these activities are ordered and coordinated to achieve the business goals. Being well considered in research and industry, this approach has led to a number of standardization efforts such as BPEL (IBM et al., 2003), XPD (WfMC, 2005), BPMN (OMG, 2006), and so forth.

As the number of services or processes involved in a business process grows, the complexity of developing and maintaining the business processes also increases along with the number of invocations and data exchanges. Therefore, it is error-prone and time consuming for developers to work with large business processes that comprise numerous concerns. This problem occurs because business process descriptions integrate various concerns of the process, such as the process control flow, the data dependencies, the service invocations, fault

handling, etc. In addition, this problem also occurs at different abstraction levels. For instance, the business process is relevant for different stakeholders: Business experts require a high-level business-oriented understanding of the various process elements (e.g., the relations of processes and activities to business goals and organization units), whereas the technical experts require the technical details (e.g., deployment information or communication protocol details for service invocations).

Besides such complexity, business experts and technical experts alike have to deal with a constant need for change. On the one hand, process-driven SOA aims at supporting business agility. That is, the process models should enable a quicker reaction on business changes in the IT by manipulating business process models instead of code. On the other hand, the technical infrastructure, for instance, technologies, platforms, etc., constantly evolves.

One of the successful approaches to manage complexity is *separation of concerns* (Ghezzi et al., 1991). Process-driven SOAs use modularization as a specific realization of this principle. Services expose standard interfaces to processes and hide unnecessary details for using or reusing. This helps in reducing the complexity of process-driven SOA models. However, from the modelers' point of view, such abstraction is often not enough to cope with the complexity challenges explained above, because modularization only exhibits a single perspective of the system focusing on its (de-)composition. Other - more problem-oriented - perspectives, such as a business-oriented perspective or a technical perspective (used as an example above), are not exhibited to the modeler. In the field of software architecture, *architectural views* have been proposed as a solution to this problem. An *architectural view* is a representation of a system from the perspective of a related set of *concerns* (IEEE, 2000). The architectural view concept offers a separation of concerns that has the potential to resolve the complexity challenges in process-driven SOAs, because it offers more tailored perspectives on a system, but it has not yet been exploited in process modeling languages or tools.

We introduce in this chapter a view-based approach inspired by the concept of architectural views for modeling process-driven SOAs. Perspectives on business process models and service interactions - as the most important concerns in process-driven SOA - are used as central views in the view-based approach. This approach is extensible with all kinds of other views. In particular, the approach offers separated views in which each of them represents a certain part of the processes and services. Some important views are the collaboration view, the information view, the human interaction view and the control flow view. These views can be separately considered to get a better understanding of a specific concern, or they can be merged to produce a richer view or a thorough view of the processes and services.

Technically, the aforementioned concepts are realized using the model-driven software development (MDSD) paradigm (Völter and Stahl, 2006). We have chosen this approach to integrate the various view models into one model, and to automatically generate platform-specific or executable code in WSDL (W3C, 2001) and BPEL (IBM et al., 2003). In addition, MDSD is also used to separate the platform-specific views from the platform-neutral and integrated views, so that business experts do not have to deal with platform-specific details. The code generation process is driven by model transformations from relevant views into executable code.

This chapter starts by introducing some basic concepts and an overview of the view-based modeling framework. Then we give deeper insight into the framework which is followed by a

discussion of view development mechanisms such as view extension, view integration and code generation mechanisms. A simple case study, namely, a Shopping process, is used to illustrate the realization of the modeling framework concepts. The chapter concludes with a discussion to summarize the main points and to broaden the presented topics with some outlooks.

OVERVIEW OF THE MODELING FRAMEWORK

In this section, we briefly introduce the View-based Modeling Framework (VbMF) which utilizes the MDSM paradigm. VbMF comprises modeling elements such as a meta-meta-model, meta-models, and models (views) (see Figure 1). In VbMF, a view (or a model) is a representation of a process from the perspective of related concerns. Each view comprises many relevant elements and relationships among these elements. The appearance of view elements and their relationships are precisely specified in a meta-model that the view must conform to. A meta-model, in turn, conforms to its meta-model, namely, a meta-meta-model (see Figure 2). A meta-meta-model is self-describing and self-conforming (Völter and Stahl, 2006). We devise a simple meta-meta-model, which is based on the meta-meta-model of the Eclipse Modeling Framework (Eclipse EMF, 2006), as the cornerstone for the modeling framework. The framework meta-models are developed on top of that meta-meta-model.

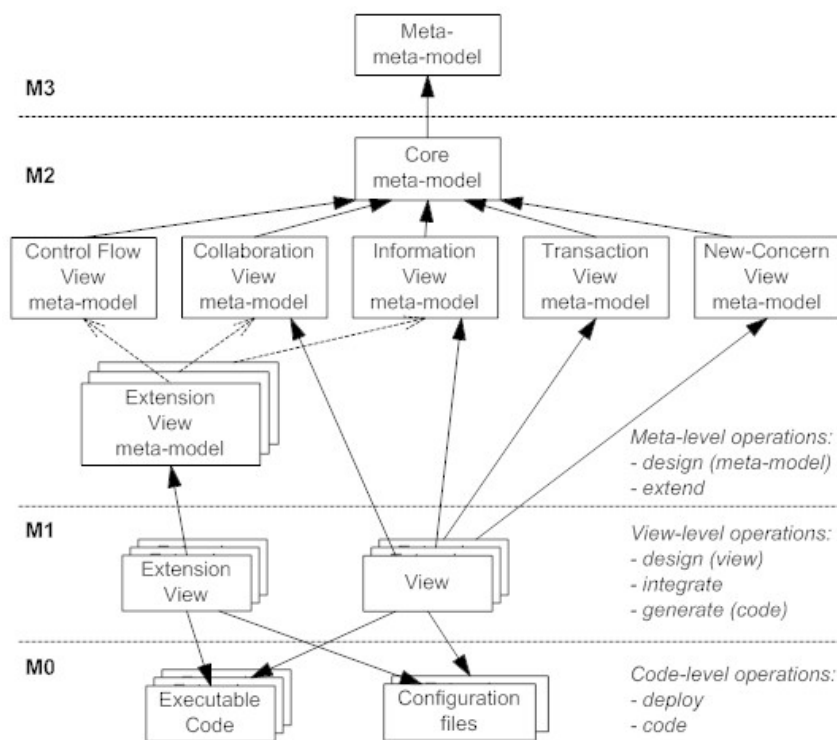

Figure 1 Overview of the View-based Modeling Framework

In our approach, we categorize distinct activities - in which the modeling elements are manipulated (see Figure 2):

- *Design* is used to define new architectural views.
- *Extend* is used to create a new meta-model by adding more features to an existing meta-model, or by developing it from scratch (e.g., to add a new formalization of a certain business process concern to the framework).
- *Integrate* is used to combine views to produce a richer view or a thorough view of a business process.

- *Transform* (or *code generation*) is used to generate executable code from one or many architectural views.

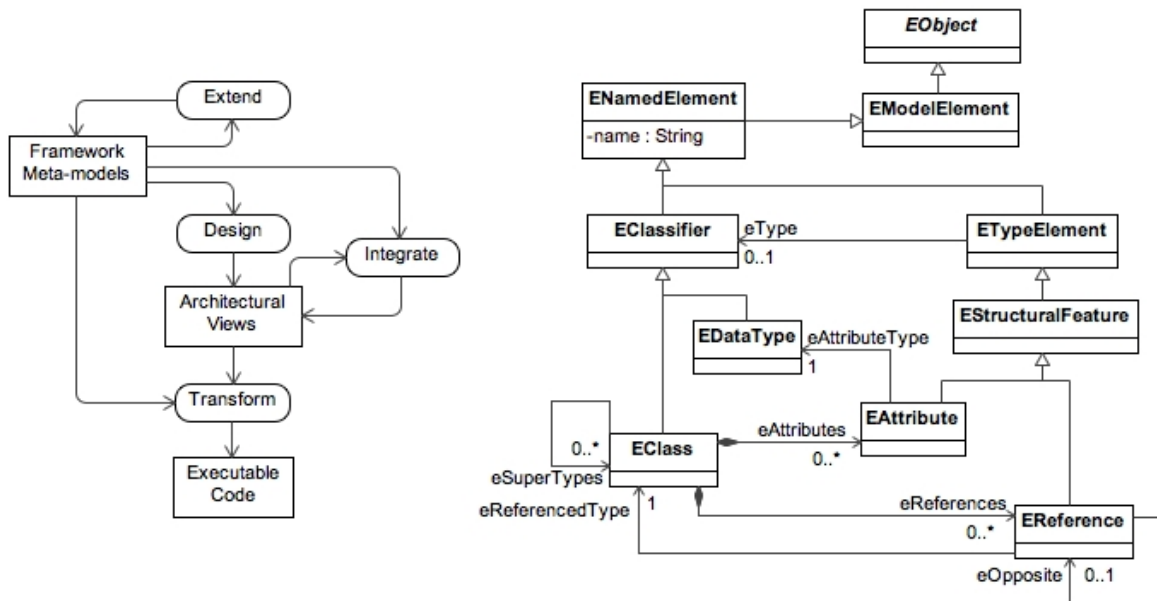

Figure 2 View-based Modeling Framework development activities (left-hand side) and the meta-meta-model (right-hand side)

Before generating outputs, the *Transform* and *Integrate* activities validate the conformity of the input views against corresponding meta-models. *Extend* and *Integrate* are the most important activities used to extend our view-based model-driven framework toward various dimensions. Existing meta-models can be enhanced using the extension mechanisms or can be merged using the meta-level integration mechanisms as explained in the subsequent sections.

VIEW-BASED MODELING FRAMEWORK

A typical business process comprises various concerns that require support of modeling approaches. In this chapter we firstly examine basic process concerns such as the control flow, data handling and messaging, and collaboration (see Figure 3). However, the view-based modeling framework is not only bound to these concerns. The framework is fully open and extensible such that other concerns, for instance, transactions, fault and event handling, security, human interaction, and so on, can be plugged-in using the same approach. In the next sections, we present in detail the formalized representations of process concerns in terms of appropriate meta-models along with the discussion of the extensibility mechanisms *Extend* and *Integrate*.

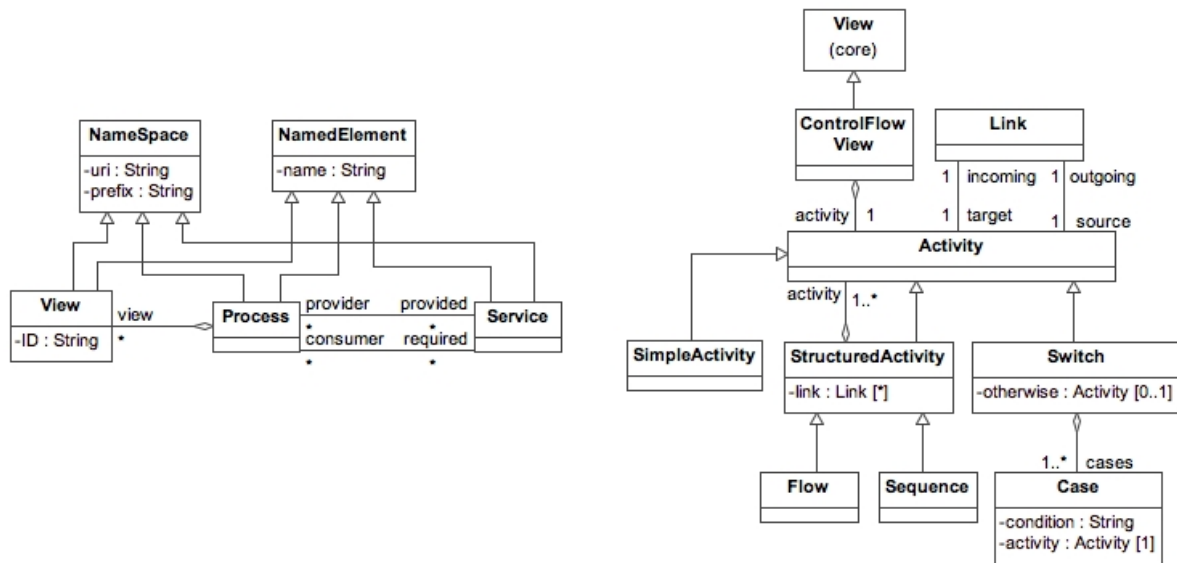

Figure 3 The Core meta-model (left-hand side) and the Control-flow View meta-model (right-hand side)

The Core meta-model

Aiming at the openness and the extensibility, we devise a basic meta-model, called the Core meta-model, as a foundation for the other meta-models (see Figure 3). Each of the other meta-models is defined by extending the Core meta-model. Therefore, the meta-models are independent of each other. The Core meta-model is the place where the relationships among the meta-models are maintained. Hence, the relationships in the Core meta-model are needed for both view- and meta-model-level integrations.

The Core meta-model provides a number of important abstract meta-classes: *View*, *Process* and *Service*. These meta-classes are derived as instances of the EClass meta-meta-class from the meta-meta-model and their relationships are derived as instances of the EAttribute or EReference meta-meta-classes, respectively. These meta-classes in the Core meta-model are cornerstones of the framework. Each of them can be extended further. At the heart of the Core meta-model is the View meta-class that captures the architectural view concept. Each specific view (i.e., each instance of the View meta-class) represents one perspective on a particular Process. A Service specifies external functions that the Process provides or requires. A View acts as a container for modeling elements representing the objects which appear inside the Process. Different instances of each of these meta-classes can be distinguished through the features of the common superclasses *NamedElement*, defining a name property, and *Namespace*, defining an URI and prefix based namespace identifier.

Because the meta-models represent concerns of a business process, they are mostly derived from the Core meta-model, and therefore these meta-classes are important extension points. The hierarchical structures in which those meta-classes are roots can be used to define the integration points used to merge meta-models as mentioned in the description of the integration mechanisms below.

Control-flow View meta-model

The control flow is one of the most important concerns of a SOA process. A Control-flow View comprises many activities and control structures. The activities are process tasks such as service invocations or data handling, while control structures describe the execution order of

the activities to achieve a certain goal. Each Control-flow View is defined based on the Control-flow View meta-model.

There are several approaches to modeling process control flows such as state-charts, block structures (IBM et al., 2003), activity diagrams (OMG, 2004), Petri-nets (Aalst et al., 2000), and so on. Despite of this diversity in control flow modeling, it is well accepted that existing modeling languages share five common basic patterns: *Sequence*, *Parallel Split*, *Synchronization*, *Exclusive Choice*, and *Simple Merge* (Aalst et al., 2003). Thus, we adopted these patterns as the building blocks of the Control-flow View meta-model. Other, more advanced patterns can be added later by using extension mechanisms to augment the Control-flow View meta-model. We define the Control-flow View meta-model and semantics of the control structures with respect to these patterns (see Table 1: Semantics of basic control structures).

Structure	Description
<i>Sequence</i>	An activity is only enabled after the completion of another activity in the same sequence structure. The sequence structure is therefore equivalent to the semantics of the <i>Sequence</i> pattern.
<i>Flow</i>	All activities of a flow structure are executed in parallel. The subsequent activity of the flow structure is only enabled after the completion of all activities in the flow structure. The semantics of the flow structure is equivalent to a control block starting with the <i>Parallel Split</i> pattern and ending by the <i>Synchronization</i> pattern.
<i>Switch</i>	Only one of many alternative paths of control inside a switch structure is enabled according to a condition value. After the active path finished, the process continues with the subsequent activity of the switch structure. The semantics of the switch structure is equivalent to a control block starting with the <i>Exclusive Choice</i> pattern and ending by the <i>Simple Merge</i> pattern.

Table 1: Semantics of basic control structures

The primary entity of the Control-flow View meta-model is the *Activity* meta-class (see Figure 3), which is the base class for other meta-classes such as *Sequence*, *Flow*, and *Switch*. Another important entity in the Control-flow View meta-model is the *SimpleActivity* meta-class that represents a concrete action such as a service invocation, a data processing task, and so on. The actual description of each *SimpleActivity* is modeled in another specific view. For instance, a service invocation is described in a Collaboration View, while a data processing action is specified in an Information View. Each *SimpleActivity* is a placeholder or a reference to another activity, i.e., an interaction or a data processing task. Therefore, every *SimpleActivity* becomes an integration point that can be used to merge a Control-flow View with an Information View, or with a Collaboration View, respectively.

The *StructuredActivity* meta-class is an abstract representation of a group of related activities. Some of these activities probably have logical correlations. For instance, a shipping activity must be subsequent to an activity receiving purchase orders. The *Link* meta-class is used in such scenarios.

Collaboration View meta-model

A business process is often developed by composing the functionality provided by various parties such as services or other processes. Other partners, in turn, might use the process. All business functions required or provided by the process are typically exposed in terms of

standard interfaces (e.g., WSDL portTypes). We captured these concepts in the Core meta-model by the relationships between the two elements Process and Service. The Collaboration View meta-model (see Figure 4) extends the Core meta-model to represent the interactions between the business process and its partners.

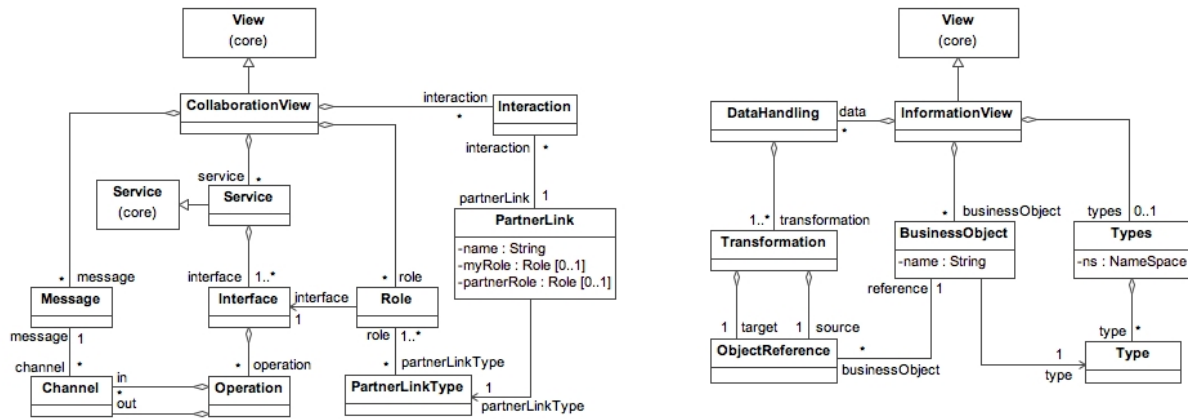

Figure 4 The Collaboration View meta-model (left-hand side) and the Information View meta-model (right-hand side)

In the Collaboration View meta-model, the *Service* meta-class from the Core meta-model is extended by a tailored and specific *Service* meta-class that exposes a number of *Interfaces*. Each *Interface* provides some *Operations*. An *Operation* represents an action that might need some inputs and produces some outputs via correspondent *Channels*. The details of each data element are not defined in the Collaboration View but in the Information View. A *Channel* only holds a reference to a *Message* entity. Therefore, each *Message* becomes an integration point that can be used to combine a specific Collaboration View with a corresponding Information View.

The ability and the responsibility of an interaction partner are modeled by the *Role* meta-class. Every partner, who provides the relevant interface associated with a particular role, can play that role. These concepts are captured by using the *PartnerLink* and the *PartnerLinkType* meta-classes and their relationships with the *Role* meta-class. An interaction between the process and one of its partners is represented by the *Interaction* meta-class that associates with a particular *PartnerLink*.

Information View meta-model

The third basic concern we consider in the context of this chapter is information. This concern is formalized by the Information View meta-model (see Figure 4). This meta-model involves the representation of data object flows inside the process and message objects traveling back and forth between the process and the external world.

In the Information View meta-model, the *BusinessObject* meta-class, which has a generic type, namely, *Type*, is the abstraction of any piece of information, for instance, a purchase order received from the customer or a request sent to a banking service to verify the customer's credit card, and so forth. Each Information View consists of a number of *BusinessObjects*. Messages exchanged between the process and its partners or data flowing inside the process might go through some *Transformations* that convert or extract existing data to form new pieces of data. The transformations are performed inside a *DataHandling*

object. The source or the target of a certain transformation is an *ObjectReference* entity that holds a reference to a particular BusinessObject.

Human View meta-model

So far we have examined different perspectives of a business process such as the control flow, the interaction with external process elements as described in the Collaboration View and the Information View. These essential views allow the specification of automated processes. If we are interested in processes that can be automated requiring no human interaction, we may use these views for designing various processes. However, business processes often involve human participants. Certain process activities need relevant human interactions. We name such process elements *Tasks*. Tasks, thus, are simple process activities that are accomplished by a person. Tasks may specify certain input values as well as a Task Description and may yield a result that can be represented using output values.

Besides the task as a special process element, the *Human View* as shown in Figure 5 defines human roles and their relations to the respective process and tasks. *Roles* are abstracting concrete users that may play certain roles. The Human View thus establishes a role-based abstraction. This role-based abstraction can be used for role-based access control (RBAC). RBAC, in general, is administered through roles and role hierarchies that mirror an enterprise's job positions and organizational structure. Users are assigned membership into roles consistent with a user's duties, competency, and responsibility.

Figure 5 The Human View meta-model

Examples for different roles are: Task Owner, Process Supervisor or Escalation Recipient. By binding, for instance, the role of a Process Supervisor to a process, RBAC can define that those users that are associated with this role, may monitor the process execution. Similarly, the owner of a task may complete the task by sending results back to the process. He may however not follow up the process.

We can specify an activity as defined within a Control-flow View to be a human Task in the Human View that is bound to for instance an owner, the person who performs the task. Likewise, process stakeholders can be specified for the process by associating them with the human view.

Extension mechanisms

During the process development lifecycle, various stakeholders take part in with different needs and responsibility. For instance, the business experts - who are familiar with business concepts and methods - sketch blueprint designs of the business process functionality using abstract and high level languages such as flow-charts, BPMN diagrams, or UML activity

diagrams. Based on these designs, the IT experts implement the business processes using executable languages such as BPEL, XPDL, etc. Hence, these stakeholders work at different levels of abstraction.

The aforementioned meta-models for the Control-flow, the Collaboration and the Information Views are the cornerstones to create abstract views. These abstract views aim at representing the high level, domain-related concepts, and therefore, they are useful for the business experts. According to the specific requirements on the granularity of the views, we can gradually refine these views toward more concrete, platform- or technology- specific views using the extension mechanisms.

A view refinement is performed by, firstly, choosing adequate extension points, and consequently, applying extension methods to create the resulting view. An extension point of a certain view is a view's element which is enhanced in another view by adding additional features (e.g., new element attributes, or new relationships with other elements) to form a new element in the corresponding view. Extension methods are modeling relationships such as generalization, extend, etc., that we can use to establish and maintain the relationships between an existing view and its extension. For instance, the Control-flow View, Collaboration View, and Information View meta-models are mostly extensions of the Core meta-model using the generalization relationship. We demonstrate the extensibility of the Collaboration View meta-model by an enhanced meta-model, namely, the BPEL Collaboration View (see Figure 6). Similar BPEL-specific view extensions have also been developed for the Information View and the Control-flow View (omitted here for space reasons).

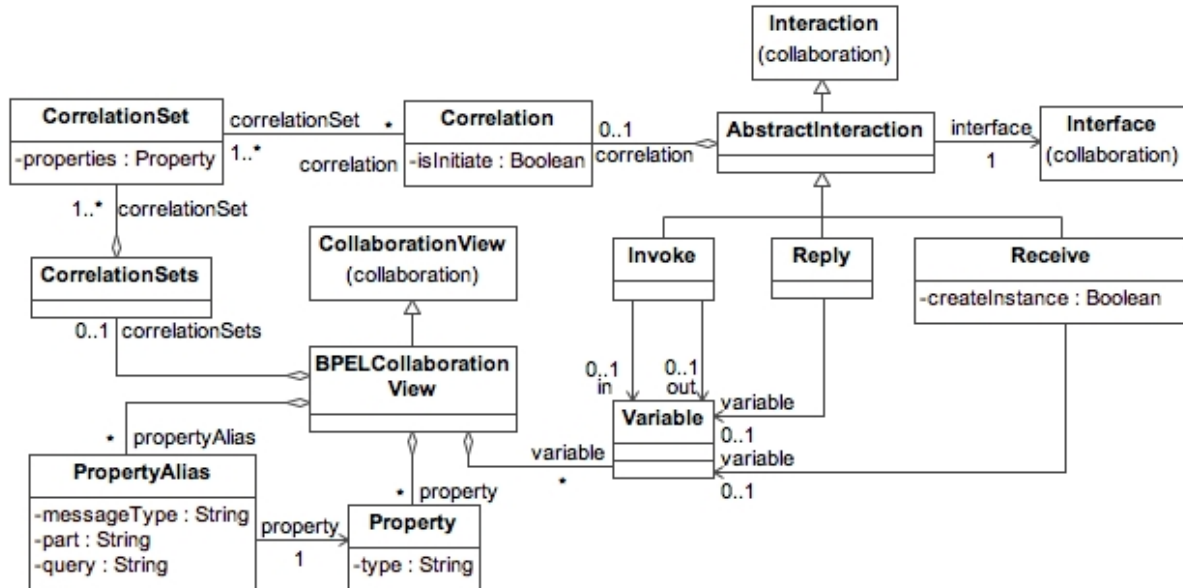

Figure 6 BPEL-specific extension of the Collaboration View

In the same way, more specific meta-models for other technologies can be derived. In addition, other business process concerns such as transactions, event handling, and so on, can be formalized by new adequate meta-models derived from the common meta-meta-model using the same approach as used above.

Integration mechanisms

In our approach, the Control-flow View - as the most important concern in process-driven SOA - is often used as the central view. Views can be integrated via integration points to provide a richer view or a thorough view of the business process (see Algorithm 1).

Definition 1

Let $M1, M2$ be two meta-models (i.e., derived from the Core meta-model). If the entities $m1 \in M1$ and $m2 \in M2$ extend the same entity of the Core meta-model, $m1$ and $m2$ are *conformable*.

Definition 2

Given $M1, M2$ are two meta-models and $V1, V2$ are two views conforming to $M1$ and $M2$, respectively. An *integration point* between $V1$ and $V2$ is a tuple $I(v1, v2 \mid v1 \in V1, v2 \in V2, v1 = \text{instanceOf}(m1), v2 = \text{instanceOf}(m2))$, and $m1$ and $m2$ are *conformable*, such that $V1$ can be merged with $V2$ - at the position of $v2$ into that of $v1$.

Algorithm 1: View integration algorithm

Input: View $V1$, View $V2$

begin

foreach entity $v1 \in V1$ **do**

$v2 \leftarrow \text{GetIntegrationPoint}(v1, V2)$;

if ($v2 \neq \text{NULL}$) **then**

$v1.\text{add}(v2.\text{eAttributes})$; /* assign all $v2$'s attributes to $v1$ */

$v1.\text{add}(v2.\text{eReferences})$; /* assign all $v2$'s references to other elements to $v1$ */

end

end

end

The *GetIntegrationPoint* function receives as input an entity $v1 \in V1$ and a view $V2$. It looks for $v2 \in V2$ such that $(v1, v2)$ is an integration point between $V1$ and $V2$. This function can be implemented based on named-based matching, class hierarchical structures, or ontology-based structures. The named-based matching mechanism might be effectively used at the view level (or model level) because from a modeler's point of view, it makes sense and is reasonable to give the same name to the modeling entities that pose the same functionality and semantics. To demonstrate the view integration idea, we present a simple implementation of the name-based matching mechanism (Algorithm 2) for the *GetIntegrationPoint* function.

Algorithm 2: Named-matching algorithm

Input: Entity $v1 \in V1$, view $V2$

Output: Entity $v2 \in V2$ or NULL

begin

 Found \leftarrow FALSE;

while NOT Found **do**

$v2 \leftarrow \text{getNextEntity}(V2)$;

if ($v2.\text{name} = v1.\text{name}$) **then**

 Found \leftarrow TRUE

end

if Found **then**

return $v2$

```
else  
    return NULL  
end
```

To create an integrated view - as the result of the view integration mechanism- a corresponding meta-model of the view has to be established first. Such a meta-model is used to validate the integrated view or to define the transformation of the integrated view into code. Therefore, an adequate integration at the meta-level is needed before any view integration or integrated view transformation. We use the same approach as given in the view integration mechanism. However, at the meta-model level, name-based matching is not sufficient. The reason is that the relationships between meta-classes are mostly hierarchical, and the meta-classes that have the same name might not be conformable. Therefore, we use class hierarchical structures to define the meta-level integration points (see Definition 3) in the view-based modeling framework.

Definition 3

Given $M1, M2$ are two meta-models based on a common meta-meta-model. A tuple $MI(m1, m2 \mid m1 \in M1, m2 \in M2)$ is a *meta-level integration point* if and only if $m1$ and $m2$ are instances of the same entity of the meta-meta-model and $M1$ can be integrated with $M2$ by merging the model structure at the position of $m2$ into that of $m1$.

Model transformations

There are two basic types of model transformations: model-to-model and model-to-code. A model-to-model transformation maps a model conforming to a given meta-model to another kind of model conforming to another meta-model. Model-to-code, so-called code generation, produces executable code from a certain model. In the view-based modeling framework, the model transformations are mostly model-to-code that take as input one or many views and generate codes in executable languages, for instance, Java, BPEL/WSDL, and so on. In the literature, numerous code generation techniques are described, such as the combination of templates and filtering, the combination of template and meta-model, inline generation, or code weaving (Völter and Stahl, 2006). In our prototype, we used the combination of template and meta-model technique which is realized in the openArchitectureWare framework (oAW, 2002) to implement the model transformations. But any other of above-mentioned techniques could be utilized in this framework with reasonable modifications as well.

CASE STUDY

To demonstrate the realization of the aforementioned concepts, we explain a simple but realistic case study, namely, a Shopping process.

The Shopping process

The Shopping process is initiated when a certain customer issues a purchase order. The purchase order is retrieved via the *ReceiveOrder* activity. The process then contacts the Banking service to validate the credit card information through the *VerifyCreditCard* activity. The Banking service only needs some necessary information such as the owner's name, owner's address, card number, and expiry date. The process performs a preparation step, namely, *PrepareVerify*, which extracts such information from the purchase order. A preparation step is often executed before an interaction on the process takes place in order to arrange the needed input data for the interaction. After validating the customer's credit card, the control flow is divided into two branches according to the validation result. In case a

negative confirmation is issued from the Bank service, e.g., because the credit card is invalid, the customer will receive an order cancellation notification along with an explaining message via the *CancelOrder* activity. Otherwise, a positive confirmation triggers the second control branch in which the process continues with two concurrent activities: *DoShipping* and *DoCharging*. The *DoShipping* activity gets delivery information from the purchase order and sends ordered products to the customer's shipping address, while the *DoCharging* activity sends a request to the Banking service for the credit card's payment. Finally, the purchase invoice is prepared and sent back to the customer during the last step, *SendInvoice*. After that, the Shopping process successfully finishes.

Figure 7 shows the Shopping process developed using BPEL. VbMF can manage several important process concerns, for example, the control flow and service collaboration, data handling, fault and event handling, and transactions. For the demonstration purpose, in this chapter we only examine the control flow and service collaborations of the Shopping process. Therefore, in Figure 7, we present appropriate BPEL code and omit irrelevant parts.

Figure 7 Case study -- the Shopping process developed using BPEL language

In the next paragraphs, we present an illustrative case study by the following steps. Firstly, the architectural views of the Shopping process are designed based on our meta-models and the sample extensions for BPEL constructs presented in the previous sections. These views are presented using the Eclipse Tree-based Editor (Eclipse EMF, 2006). Secondly, some views are integrated to produce a richer perspective. And finally, these views are used to generate executable code in WS-BPEL and WSDL that can be deployed into a BPEL engine.

View development

Figure 8 shows the Control-flow View of the Shopping process. There are no details of data exchanges or service communication in this view. Hence, the Control-flow View can be used by the stakeholders who need a high level of abstraction, for instance, the business experts or the domain analysts.

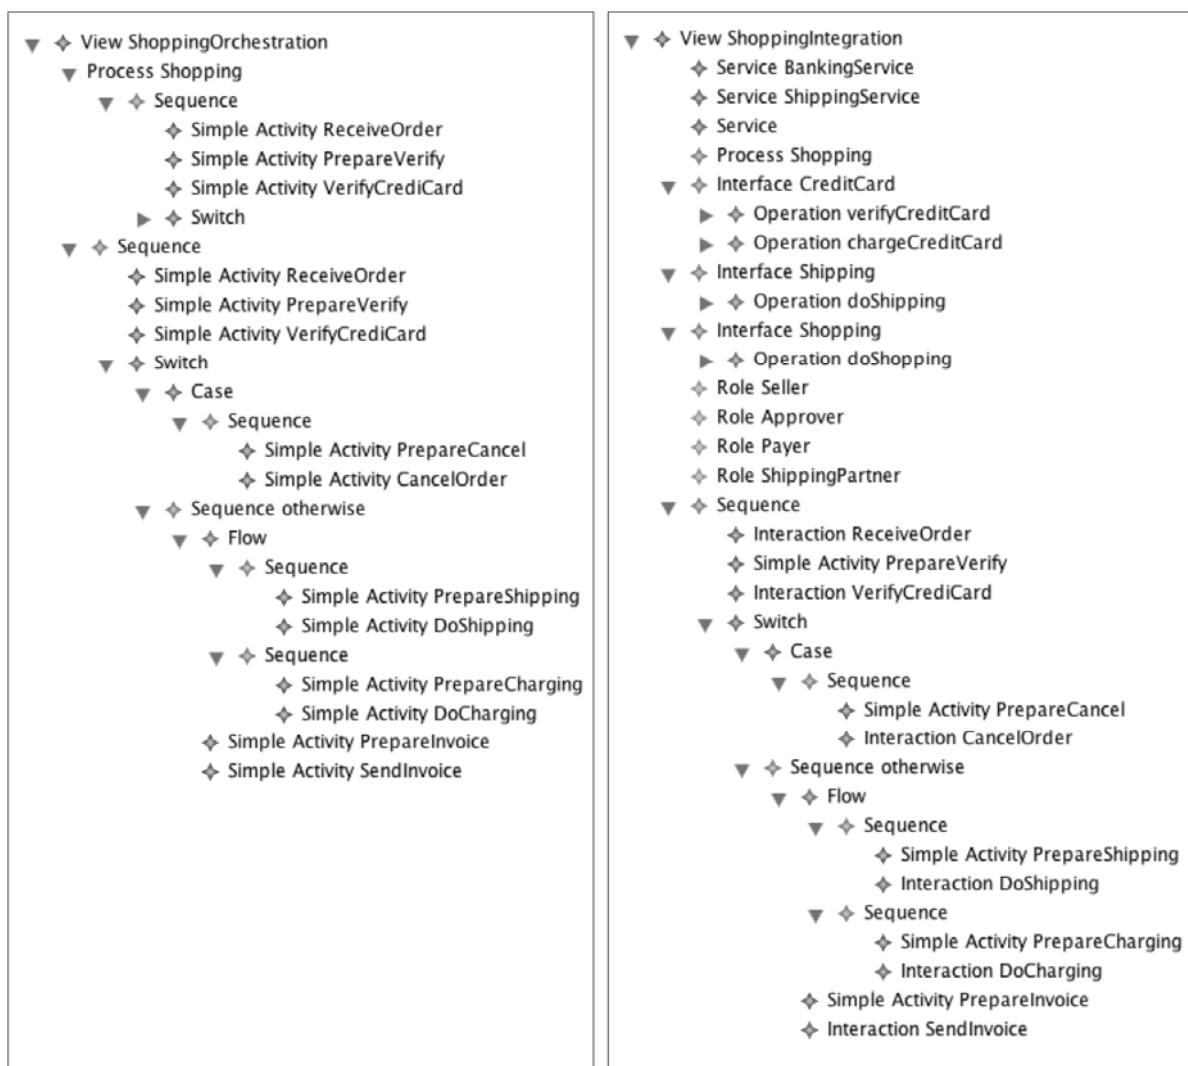

Figure 8 The Control-flow View (left-hand side) and an integrated view of the Shopping process – the result of integration the Control-flow View and the Collaboration View (right-hand side).

Moreover, using the extension meta-models (e.g., the BPEL-specific extension of the Collaboration View given in Figure 6), the technical experts or the IT developers can develop much richer views for a particular concern. In Figure 9, there are two models side by side in which one is the abstract collaboration model (i.e., the left-hand side view in Figure 9) and

another one, which is at the right-hand side in Figure 9, is a view based on the BPEL Collaboration meta-model.

View integration

The views also can be integrated to produce new richer views of the Shopping process. At the right-hand side of Figure 9, we present an integrated view which is the result of the combination of the Control-flow View and the Collaboration View of the Shopping process. The SimpleActivity entities in the Control-flow View define the most important integration points with relevant Interaction entities in the Collaboration view. The output view consists of control structures based on the Control-flow View and additional collaboration-related entities such as Roles, Services, etc. Moreover, relevant activities of this view also comprise additional collaboration-specific attributes.

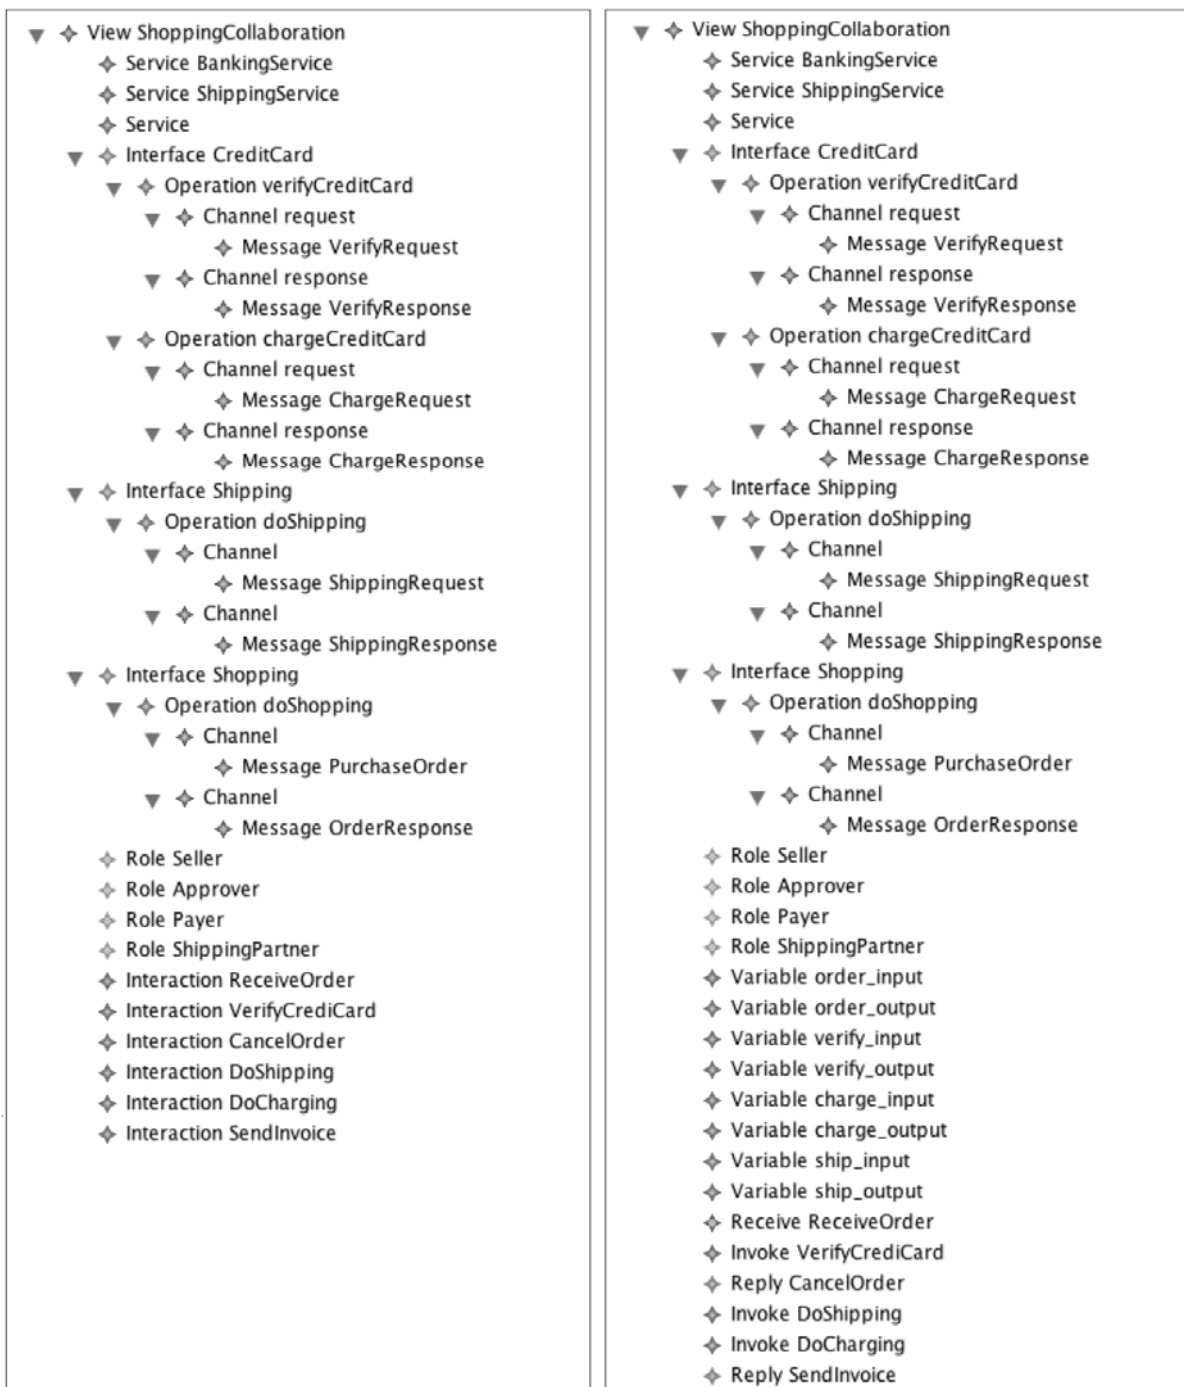

Figure 9 The Collaboration View (left-hand side) and the corresponding BPEL-specific extension view of the Collaboration View (right-hand side) of the Shopping process.

Code generation

After developing appropriate views for the Shopping process, we use illustrative template-based transformations to generate executable code for the process in BPEL and a service description in WSDL that represents the provided functions in terms of service interfaces. The modeling framework's models and Shopping process's models are Ecore models. We used the oAW's Xpand language to define the code generation templates (see Figure 10).

```

#
# Template for the main process
#

```

Figure 10 Template in oAW's Xpand language for generating BPEL code from the Control-flow View and the BPEL-specific extension of the Collaboration View

We present a model transformation (aka code generation) snippet in oAW's Xpand language that generates executable code in BPEL language for activities such as Invoke, Receive and Reply using the BPEL-specific extension view given in Figure 6. The resulting executable code in BPEL and WSDL has been successfully deployed on the Active BPEL Engine (Active Endpoints, 2006) and Apache Orchestration Director Engine (Apache, 2007).

CONCLUSION

Existing modeling approaches lack sufficient support to manage the complexity of developing large business processes with many different concerns because most of them consider the process model as a whole. We introduced in this chapter a view-based framework that precisely specifies various concerns of the process model and uses those models to capture a particular perspective of the business process. It not only helps to manage the development complexity by the separation of a business process's concerns, but also to cope with both business and technical changes using the separation of levels of abstraction. The proposed modeling framework can possibly be extended with other concerns of the business process such as security, event handling, etc., to cover all relevant concepts and process development technologies.

SUGGESTED ADDITIONAL READING

There are several standardization efforts for process modeling languages, such as BPEL (IBM et al., 2003), BPMN (OMG, 2006), XPD (WfMC, 2005), and so on. They can be categorized into different dimensions, for instance, textual and graphical languages, or abstract and executable languages. Most of these modeling languages consider the business process model as a whole, and therefore, do not support the separation of the process model's concerns. All these modeling languages can be integrated into the view-based modeling approach using extension models.

The concept of architectural views (or viewpoints) has potential of dealing with software development complexity, and therefore, is well-known in literature, for instance, the Open Distributed Processing Reference Model proposed in ISO (1998), or UML modeling language specified in UML (2003), to name a few. However, this concept has not been exploited in the field of business process development, and particularly, in process-driven SOA modeling. Axenath et al., (2005) present the AMFIBIA framework as an effort on formalizing different aspects of business process modeling, and propose an open framework to integrate various modeling formalisms through the interface concept. Akin to the approach presented in this chapter, Amfibia has the main idea of providing a modeling framework that does not depend on a particular existing formalism or methodology. The major contribution in AMFIBIA is to exploit dynamic interaction of those aspects. Therefore, the distinct point to VbMF is that in AMFIBIA the interaction of different “aspects” is only performed by event synchronization at run-time when the workflow management system executes the process. Using extension and integration mechanisms in VbMF, the integrity and consistency between models can be verified earlier at the model level.

In this chapter, we also exploit the model-driven software development (MDS) paradigm, which is widely used to separate platform-independent models from platform-specific models, to separate different levels of abstraction in order to provide appropriate adapted and tailored views to the stakeholders. Völter and Stahl (2006) provide a bigger, thorough picture about this emerging development paradigm in terms of the basic philosophy, methodology and techniques as well. Through this book, readers achieve helpful knowledge on basic terminologies such as meta-modeling, meta-meta-model, meta-model, model, platform-independent and platform-specific models, and modeling techniques such as model transformation, code generation as well.

Human interaction with SOAs have lately been formalized in The WS-BPEL Extension for People (BPEL4People) (Agrawal et al., 2007b). BPEL4People defines a *peopleActivity* as a new BPEL *extensionActivity* and thus realizes integration of human process activities into BPEL processes. BPEL4People is based on the WS-HumanTask specification that introduces formal definition of human tasks. Various roles for processes and tasks are defined in BPEL4People as well as WS-HumanTask that users can be assigned to for role-based access control.

KEY TERMS

Architectural view: a view is a representation of a whole system from the perspective of a related set of concerns (IEEE, 2000)

Service Oriented Architecture (SOA): a architectural style in which software components or software systems operate in a loosely-coupled environment, and are delivered to end-users in terms of software units, namely, services. A service provides a standard interface (e.g., service interfaces described using WSDL), and utilizes message exchange as the only communication method.

Separation of concerns: the process of breaking a software system into distinct pieces such that the overlaps between those pieces are as little as possible, in order to make it easier to understand, to design, to develop, to maintain, etc., the system.

Business process modeling: a process of designing, implementing, and executing of business processes. Business process modeling sometimes is referred as business process management.

Process modeling language: a formal or semi-formal language used through business process development life-cycle. Process modeling languages can be categorized into abstract

language (e.g., BPMN) or executable language (e.g., BPEL); textual language (e.g., BPEL, XPDL) or graphical language (e.g., BPMN), and so on.

Model-driven Software Development (MDSO) or Model-driven Development (MDD): a paradigm that advocates the concept of models, that is, models will be the most important development artifacts at the centre of developers' attention. In MDSO, domain-specific languages are often used to create models that capture domain abstraction, express application structure or behavior in an efficient and domain-specific way. These models are subsequently transformed into executable code by a sequence of model transformations (Völter and Stahl, 2006).

Model and meta-model: a model is an abstract representation of a system's structure, function or behavior. A meta-model defines the basic constructs that may occur in a concrete model. Meta-models and models have a class-instance relationship: each model is an instance of a meta-model (Völter and Stahl, 2006)

Model transformation: transformation maps high-level models into low-level models (aka model-to-model transformations), or maps models into source code, executable code (aka model-to-code or code generation).

Role-based Access Control (RBAC): Access control decisions are often based on the roles individual users take on as part of an organization. A role describes a set of transactions that a user or set of users can perform within the context of an organization. RBAC provide a means of naming and describing relationships between individuals and rights, providing a method of meeting the secure processing needs of many commercial and civilian government organizations (Ferraiolo et al., 1999).

Web Service Description Language (WSDL): a standard XML-based language for describing network services as a set of endpoints operating on messages containing either document-oriented or procedure-oriented information. The operations and messages are described abstractly, and then bound to a concrete network protocol and message format to define an endpoint. WSDL is extensible to allow description of endpoints and their messages regardless of what message formats or network protocols are used to communicate (W3C, 2001)

Stakeholder: In general, stakeholder is a person or organization with a legitimate interest in a given situation, action or enterprise. In the context of this chapter, stakeholder is a person who involved in the business process development at different levels of abstraction, for instance, the business experts, system analysts, IT developers, and so forth.

EXERCISES

For the exercises completing this chapter, we are using the following scenario:

At a rescue center rescue missions are controlled. Each emergency call is answered by a co-ordinating officer and is recorded by the control center system. If not supplied by the caller, the officer asks for the following information:

- What happened?
- Who is calling? How can the caller be contacted?
- Where did the accident happen?
- How many people are injured?

After the call, the officer assigns a rescue team to the mission and sends him a short description together with the location via, for instance, a Short Data Service (SDS). The rescue team confirms acceptance of the mission by sending a status code '2'. At arrival it notifies the rescue center with status code '3'. After first aid measures, the team prepares to

make the patient transportable. When leaving the location the status code is updated to '4'. At the arrival at the hospital with further medical treatment the status is set to '5'. After the team has prepared for standby the rescue center is notified with a status '6'.

Beginner

- Describe the human task of receiving an emergency call. What are the in- and outputs and who may and who may, for example, not perform this task? Define some human roles and describe the relations between them and human tasks as well as the process.
- Formulate the control flow of the described rescue mission using an UML activity diagram.

Intermediate

- Identify the different participants that are involved in the rescue mission and draw a BPMN diagram for the rescue mission.
- Improve the process and provide means for also alerting a fire brigade if necessary. For close collaboration the process itself invokes an external activity by passing the information of the rescue operation.

Advance

- A company wants to optimize one of its business workflows. Therefore out of a process with about 20 elements a sub-process containing 5 process elements are being out-sourced. How do the process models change? Using the view-based approach, what views do you need to modify and where do you need to specify additional information?

Practical Exercises

- Specify XML schemata for the messages that are being sent and extend them with chronological information.

BIOGRAPHIES

Huy Tran is a PhD student in the Distributed System Group at the Information Systems Institute, Vienna University of Technology, Austria. His research interests include service-oriented computing, model-driven software development and business process management.

Ta'id Holmes is a PhD student in the Distributed System Group at the Institute of Information Systems, Vienna University of Technology, Austria. Ta'id is also a guest lecturer at the Vienna University of Economics and Business Administration. Ta'id received a Dipl.-Ing. from the Vienna University of Technology in Software Engineering/Internet Computing and a D.E.A. in Chimie Organique Fine from the Université Claude Bernard Lyon 1. Ta'id's research interests include distributed systems, model driven development and domain specific languages.

Uwe Zdun is an assistant professor at the Distributed Systems Group, Information Systems Institute, Vienna University of Technology, Austria. Prior to that, Uwe has worked as an assistant professor in the Department of Information Systems at the Vienna University of Economics and BA, Austria. His research interests include software patterns, software architecture, SOA, distributed systems, language engineering, and object orientation. He received his doctoral degree in computer science from the University of Essen in 2002, and his habilitation degree (venia docendi) from Vienna University of Economics and BA in 2006. He is coauthor of the books *Remoting Patterns* (John Wiley & Sons, 2004) and *Software-Architektur* (Elsevier/Spektrum, 2005).

Schahram Dustdar is a Full Professor for Internet Technologies at the Distributed Systems Group, Information Systems Institute, Vienna University of Technology (TU Wien) where he is director of the Vita Lab and Honorary Professor of Information Systems at the Department of Computing Science at the University of Groningen (RuG), The Netherlands. He received his M.Sc. (1990) and PhD. degrees (1992) in Business Informatics (Wirtschaftsinformatik) from the University of Linz, Austria. In April 2003 he received his habilitation degree (venia docendi).
